

Salesforce → Trackon Contract Integration

Phase 1 (Design & Discovery) closure — the confirmed architecture, security model, live master-data feed, reference-data design, and the contract-creation API design for the Phase 2 build.

Prepared for Justin Evans & Chad Shumate · DFA / Mana

Trackon Software FZCO · Bibeesh Rathnapal · Murat Selim Ozturk

PHASE 1 · DESIGN & DISCOVERY

What Phase 1 delivered

- Integration pattern & security model confirmed with DFA IT — **and already live**
- Master-data feed (customers & vendors) — **live, verified end-to-end with DFA credentials**
- API credentials issued and handed to DFA (14 Aug working session)
- Field-mapping ownership settled per field (14 Aug working session)
- Drop-down option lists delivered with Trackon IDs
- Reference-data design — how picklists stay current (this document)
- Contract-creation API design (this document)
- Contract approval flow — **two options, joint decision at the review call**

Everything marked green is done. This document records the design; the accompanying proposal prices the Phase 2 build.

CONFIRMED SCOPE

The agreed model — unchanged

Contracts

SALESFORCE → TRACKON

Approved contracts flow **one way** from Salesforce into Trackon. After creation, all edits, **amendments** and **cancellation / termination** happen in Trackon only. Trackon is the system of record.

Master data

TRACKON → SALESFORCE

LIVE

Trackon is the **master** for customers and vendors. Salesforce pulls status, payment terms, credit limits and addresses from the live Trackon API so the front end stays current.

One way in each direction. No two-way sync, no conflicting edits to reconcile — exactly as agreed in June and confirmed at kickoff.

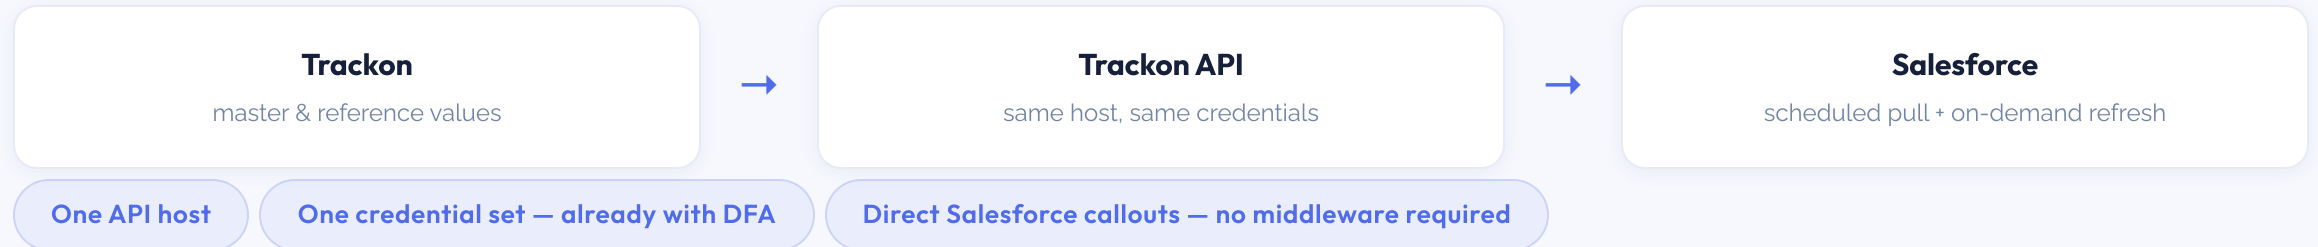

ARCHITECTURE

How the pieces connect

CONTRACT CREATION · PHASE 2

MASTER & REFERENCE DATA · MASTER DATA LIVE TODAY

SECURITY · LIVE AND VERIFIED

Security design

- **OAuth 2.0 client-credentials** — Salesforce obtains a short-lived token from the token endpoint, then calls the data endpoints. Standard Named Credential setup on the Salesforce side.
- **TLS everywhere** — all traffic over HTTPS on api.trackonsoftware.com; plain HTTP redirects to HTTPS.
- **Dedicated integration credentials** — the DFA/Salesforce client is scoped to this integration's endpoints only, revocable independently of any other consumer.
- **Minimal surface** — the API host serves only the integration endpoints; everything else returns 404. Only the agreed business fields are exposed.
- **Rate limiting** — request-rate protection at the edge; well within normal integration traffic.
- **Scoped data serving** — active, Dubai-branch counterparties only, matching the reference files DFA already holds.

This posture is live and was verified end-to-end with DFA's own credentials — token issuance, authenticated reads, and correct 401/404 behavior from the public internet.

Customers & vendors feed

```
POST /mana/oauth/token    - OAuth 2.0 token (client credentials)
GET  /mana/v1/customers  ·  /mana/v1/customers/{id}
GET  /mana/v1/vendors    ·  /mana/v1/vendors/{id}
```

- **Pull model** — Salesforce pulls on its own schedule; pagination and delta filtering supported for efficient syncs.
- **Same keys as your reference files** — records carry the same Main Account / Sub Account / Contact IDs as the Excel files DFA already mapped against.
- **Active records only** — a counterparty absent from a full pull has been deactivated in Trackon; Salesforce should deactivate its copy.
- **Fields per agreed scope** — names, status, payment terms, credit limits, addresses. Changes always originate in Trackon.

Full request/response detail, pagination and error codes are in the API Integration Guide already shared with Chad's team.

Who maps what

FIELD	MAPPING	AGREED APPROACH
Product Line	In Trackon	Derived from the product Salesforce sends
Department / Sub Department	In Trackon	Derived from the trader Salesforce sends
Branch	In Trackon	Mapped inside Trackon
Trader	Done	Mapping already with DFA's Salesforce team
Container Type	None needed	Salesforce values match Trackon — sent as-is
Currency · Product · Packing	Trackon lists	Picklists in SF from Trackon option lists, ID recorded
Loading / Destination Port	Trackon lists	Picklists in SF from Trackon option lists, ID recorded
Payment Terms	Trackon lists	Recorded in SF, sent to Trackon as Trackon ID

Salesforce always stores the **Trackon ID**; display labels are cosmetic. This keeps every contract payload unambiguous.

Picklists that never go stale

The option lists delivered today are a [snapshot](#). Payment terms are added by Trackon users from time to time; ports and products evolve with trade patterns. Maintaining these by hand in Salesforce would drift within weeks — so Phase 2 exposes them as [reference-data endpoints](#) on the same API:

```
GET /mana/v1/reference/payment-terms · currencies · products · packing · ports
– each returns the current option set: Trackon ID, display value, attributes
```

Same host & credentials as today

Full set per call — simple to consume

IDs stable over time

Two refresh patterns

Option A · Live lookup

Salesforce queries the reference API **at contract-entry time**. Values are always current, but every picklist interaction depends on an external callout inside the data-entry flow — added latency, and entry blocks if the connection is briefly unavailable.

Option B · Scheduled + on-demand **RECOMMENDED**

A **nightly Salesforce job** refreshes the picklists from the API. Alongside it, a **"Refresh from Trackon" button** for the Salesforce admin: when a trader needs a payment term just created in Trackon, the admin clicks refresh and it is available **within a minute** — no waiting for the nightly run, no manual maintenance ever.

We recommend Option B: reference values change occasionally, not constantly — a cached picklist with a one-click urgent refresh gives traders a fast entry form *and* same-day access to new values.

The contract-creation API

A single endpoint accepts the complete contract in **one JSON payload** and creates it in **one transaction** — through Trackon's own business rules, exactly as a contract entered on a Trackon screen. Either the whole contract is created, or nothing is.

PAYLOAD GROUP	CONTENTS
Header	Contract type, counterparty (Trackon ID), trader, dates, currency, branch context
Products & quantities	Product (Trackon ID), quantity, packing, tolerances
Pricing & payment	Price terms, payment terms (Trackon ID), premiums where applicable
Quality	Quality parameters per product, defaults from the product master where not sent
Logistics	Loading / destination ports (Trackon IDs), container type, shipment periods
Clauses	Selected by reference — Salesforce sends clause IDs; wording, documents and printing stay in Trackon

Idempotent — safe retries via a Salesforce-supplied reference ID

Clear per-field validation errors back to Salesforce

Approval flow — two options

Option 1 · Approved on arrival

Salesforce sends the contract **after SF approval**; Trackon creates it directly in approved status. Simplest flow — but the contract document (clauses, print) is only produced *after* approval, so any clause adjustment means handling it in Trackon post-approval.

Option 2 · Draft, then approve in Trackon

Salesforce sends the contract at SF approval; Trackon creates it as a **draft**, the team finalises clauses and prints, then approves in Trackon. One extra step — but the printed contract is reviewed before it becomes binding in the system of record.

Both are fully supported by the same API — this is a **workflow choice, not a cost difference**. We'll walk through both at the review call and lock one before the build starts.

WHEN SOMETHING FAILS

Exceptions — never silent

- **Immediate response to Salesforce** — validation failures return specific, per-field errors so DFA's side can log and surface them.
- **Exceptions console in Trackon** — any contract that arrives but cannot be created cleanly (e.g. a blocked counterparty, missing reference value) is queued on a Trackon screen for a user to resolve and re-process in place.
- **Safe retries** — the Salesforce reference ID makes re-sends idempotent: a retried contract is never created twice.
- **Monitoring** — integration traffic and failures are monitored on the Trackon side as part of the support arrangement.

The principle from the June proposal, unchanged: flagged for a person to resolve — never silently rejected.

FOR CLARITY

Assumptions & open items

- **Field-mapping workbook** — the Phase 2 fixed price assumes the field set per this document (14 Aug session). DFA's field-mapping workbook and functional spec, mentioned at kickoff, will be used to confirm it; material additions would be scoped separately.
- **Approval flow** — Option 1 or 2 to be locked at the review call; no cost impact either way.
- **Salesforce side** — DFA IT builds the approval trigger, the callout, picklist setup and the refresh job/button; Trackon provides the endpoints and documentation.
- **Sandbox** — the dedicated Salesforce sandbox for integration testing (Chad, kickoff) available at the start of the build.
- **Clauses & documents** — clause wording, document generation and printing remain in Trackon; Salesforce selects by reference.

NEXT STEPS

From design to build

Phase 1 is complete. Three steps take us to the December go-live:

- **Review call** — walk through this document and the Phase 2 proposal; lock the approval flow; confirm the field mapping against DFA's workbook.
- **Phase 2 acceptance by 4 September** — protects ~10 weeks of development plus UAT, training and contingency before December.
- **Build starts immediately on acceptance** — the API platform, credentials and sandbox path are already in place.
